

H. Gulf of Maine/Georges Bank American Plaice by L. O'Brien, J. Burnett, and L. Col

1.0 Background

This stock was last assessed in 2002 (O'Brien et al. 2002) and reviewed by the Groundfish Assessment Review Meeting (Northeast Fisheries Science Center 2002).

Landings in 2001 were 4,479 mt and fully recruited F (ages 5-8, u) in 2001 was estimated to be 0.43, a 30% increase from 2000. Spawning stock biomass was 13,822 mt in 2001, a decrease of 3% from 2000. The 1998 and 2001 year classes were above average and the 2000 year class was the lowest in the time series.

2.0 Fishery

Total commercial landings of Gulf of Maine-Georges Bank American plaice were 1,711 mt in 2004, a 31% decrease from 2003 and a 51% decrease from 2002 (Table H1, Figure H1). USA landings account for about 98% of the landings in recent years (2002-2004) and Canada accounts for the remainder. The otter trawl fleet accounts for more than 95% of the landings and the fishery is prosecuted primarily during the 2nd and 3rd calendar quarter of the year. The highest proportion of landings are in the small market category. The number of samples obtained for characterizing the catch at age were adequate during 2002-2004, however, landings had to be pooled by half-year in 2002 for the medium market category (Table H2). The total catch at age (Table H3, Figure 2) includes estimates of discarded fish from both the Northern shrimp fishery and the large mesh fishery and landings from the commercial fishery.

Discarding of small fish occurs in the northern shrimp fishery during the 1st and 4th calendar quarter, and year-round by the large mesh fishery. Discarded catch in the Northern shrimp fishery is estimated directly from sea-sampled trips (1989-1997) and indirectly using survey data (1980-1988, 1998-2004). Discards in the large mesh fishery are also estimated based on survey data. During 2002-2004 discards in the shrimp fishery accounted for about 0.8% of the total catch (in numbers) and discards in the large mesh fishery account for about 23% of the total catch (in weight).

3.0 Research Surveys

The NEFSC survey indices of abundance and biomass have generally been increasing during 1988-2000. The most recent spring and autumn indices, however, both indicate a decreasing trend (Table H4, Figure H3 and H4) during 2000-2005. Recruitment indices of age 1 fish from NEFSC autumn surveys indicate that both the 1997 and 1998 year classes are above average and the 2001 year class is just about average (Fig. H5a). The 1997 and 1998 year classes are just below average in the autumn Massachusetts state survey, however the 2003 is above average (Fig H5b).

4.0 Assessment

Input data and Analyses

The current assessment is an update assessment and employs the same ADAPT formulation as in the 2002 assessment (O'Brien *et al.* 2002). Catch at age has been updated with 2002, 2003, and 2004 landings, and discards have been estimated for the Northern shrimp fishery and the large mesh fishery. Research survey indices have been estimated for the spring NEFSC (ages 1-8) and MADMF (ages 1-5) surveys and the autumn NEFSC (ages 1-6) and MADMF (ages 1-5) surveys for 2002-2004 (Table H5a-d). The ADAPT calibration method (Parrack 1986), (Gavaris 1988), (Conser and J.E. Powers. 1990) was used to derive estimates of instantaneous fishing mortality and beginning year stock sizes in 2004. A conditional non-parametric bootstrap procedure (Efron 1982) was used to evaluate the precision of fishing mortality, spawning stock biomass, and mean biomass estimates. A retrospective analysis was performed for terminal year fishing mortality, spawning stock biomass, and age 1 recruitment.

Assessment results

Fully recruited fishing mortality (age 5-8) was estimated at 0.15 in 2004 (Table H6, Figure H6). Spawning stock biomass in 2004 was estimated at 14,149 mt, a 16% decrease from 2001 and a 10% decrease from 2003 (Table H6, Figure H7). Recruitment of the 2001 year class (32.4 million age 1 fish) is estimated to be similar to the above average 1998 year class (35.7 million age 1 fish). The 2003 (54.8 million age 1 fish) and 2004 (66.7 million age 1 fish) year classes are well above the long term average (33.1 million age 1 fish) (Table H6, Figure H7).

VPA Diagnostics

Stock size estimates for ages 1-8 were well estimated with CVs ranging from 0.16 to 0.44. The distribution of F estimates from the bootstrap analysis ranged from 0.12 to 0.20 with an 80% probability that F in 2004 was between 0.14 and 0.17. The distribution of SSB estimates from the bootstrap analysis ranged from 12,000 mt to 18,000 mt with an 80% probability that SSB in 2000 was between 13,000 mt to 16,000 mt.

The retrospective analysis indicates a pattern in the estimate of F and SSB with this model formulation (Figure H8). The terminal year estimates of fishing mortality exhibit a pattern of overestimating F before 2003, whereas, SSB has a pattern of underestimation before 2003. The terminal year estimates of recruits are underestimated prior to 2002 and overestimated after 2002. These patterns are very different from the previous assessment (O'Brien *et al.* 2002) in which there was not a strong retrospective pattern .

5.0 Biological Reference Points

Biological reference points were established for Gulf of Maine -Georges Bank American plaice based on yield per recruit analyses using $F_{40\%}$ as a proxy for F_{MSY} (NEFSC 2002) as:

$MSY = 4,900 \text{ mt}$
 $SSB_{MSY} = 28,600 \text{ mt}$ and
 $F_{MSY} = 0.166$

In 2004, spawning stock biomass was estimated at 14,149 mt, about 49% of the target SSB_{MSY} . The stock is considered to be overfished, although the upper 80% confidence interval includes biomass >50% SSB_{MSY} . Overfishing is not occurring on this stock since $F_{2004} = 0.15 < F_{MSY}$, although the upper 80% confidence interval about F_{2004} is above F_{MSY} .

6.0 Summary

American plaice in the Gulf of Maine-Georges Bank region are overfished but overfishing is not occurring. Estimates of F and SSB are similar to the A13 projection trajectories for 2002-2004 (Figure H9). Fishing mortality on this stock has declined during 2001-2004. Spawning stock biomass increased during 1995 to 2000 to 16,815 mt and has since decreased to 14,149 mt in 2004. The 1998 and 2001 year classes are just above average, whereas the 2000 year class is the lowest on record. The 2003 and 2004 year classes are well above average. The NEFSC survey biomass indices show a declining trend during 2002-2005, however, the 2001 and 2003 and 2004 year classes appear to be at or near the long term average.

7.0 Sources of Uncertainty

Lack of direct estimates of discards from sea sampled trips for large mesh fishery and shrimp fishery.

8.0 Panel Discussion

The Panel noted that discards from the northern shrimp fishery and the large-mesh otter trawl fishery estimated using survey-based methods are likely to be more uncertain than those estimated directly from Observer data. While the survey-based methods are consistent with previous American plaice assessments, direct estimates based on observer data are desirable.

The Panel discussed the number of fish estimated at age 1 in 2004 (68 million fish) and noted that there is some uncertainty associated with this estimate (bootstrap CV 93%). The high CV, coupled with the retrospective pattern of overestimating recruits, indicate that future assessments may estimate a lower value for this year class.

The Panel noted the retrospective analysis indicated a weak pattern where F was overestimated, spawning stock biomass was underestimated and estimates of Age 1 were underestimated prior to 2002 and overestimated after 2002.

Projection Advice - Given the declining trend in mean weights at age, the Panel agreed that the average of the three most recent years (2002 - 2004) of mean weights at age should be used for short-term projections. Additionally, a 'smoothed' partial recruitment vector based on 2002 -

2004 and the most recent maturity stanza (2003 - 2005) should be used. Although Age 1 in 2004 (2003 year class) is poorly estimated, this year class will not be influential on the short-term projected estimates of spawning stock biomass, and so the Panel agreed to retain the estimated value. The Panel agreed that re-sampling from the entire recruitment series should be used in the short-term projections.

Table H6. Estimates of beginning year stock size (thousands of fish), instantaneous fishing mortality (F), spawning stock biomass (mt), and percent mature of Gulf of Maine-Georges Bank American plaice, estimated from virtual population analysis (VPA), calibrated using the commercial catch at age ADAPT formulation, 1980-2004.
